Jane Street Puzzle May 2026

Andrew Ely

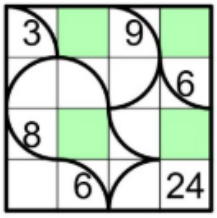

---

example grid

(solved)

(cells filled in)

example answer = **18,928**

Draw 90-degree arcs in some of the white cells. Arcs may not go in green cells. An arc has radius 1, connecting one corner of a cell to the opposite corner. (A cell may contain at most one arc.)

When finished, the arcs must divide the grid into **regions**, and those regions must have **integer area**. (Arcs are not allowed to "dangle" – that is, the two parts of a cell containing an arc must belong to distinct regions.)

For each region, compute the number of "smooth" (continuously differentible) pieces that comprise its perimeter. Multiply that number by the region's area to get its SCORE.

A cell labeled with a number indicates the score of the region that contains at least half (and possibly all) of that cell.

After completing the grid, fill each of the un-numbered cells with the score of the region that contains at least half of that cell. The answer to this month's puzzle is the sum of the *squares* of the row sums, **plus** the sum of the *squares* of the column sums. (As in the example.)
